Targeting the CD11a adhesion molecule `could be of major interest in the manipulation of the graft recipient's immune system', say French researchers. They found that prophylactic use of an antibody directed against CD11a was effective in preventing early rejection in renal allograft recipients, in the first such study to be conducted.

15 patients received the anti-CD11a antibody 10-20 mg/day, corticosteroids and azathioprine for 10 days after renal transplantation. Cyclosporin was introduced on day 8. Corticosteroid treatment. . . the first 3 months, but all kidneys remained functional during 12-19 months of follow-up.

The antibody was very well tolerated. Transient fever was experienced by 6 patients, and ALT levels were slightly raised in 5.
